The screenshot shows a web browser window displaying the 'Demos' section of the Pennylane website at <https://pennylane.ai/qml/demonstrations/>. The browser interface includes a back/forward button, a search bar, and various tabs. The main content area features a heading 'New demos' above three cards:

- Intro to the Quantum Fourier Transform**: A card featuring a blue and pink wavy graphic with the letters 'QFT'. It includes 'Algorithms' and 'Quantum Computing' tags.
- Efficient Simulation of Clifford Circuits**: A card featuring a geometric diagram with a central point and several lines, with a yellow flame effect on the right. It includes 'Devices and Performance' tags.
- Gate calibration with reinforcement learning**: A card featuring a blue robot-like character interacting with a quantum circuit. It includes 'Getting Started', 'Optimization', and 'Quantum Hardware' tags.

Below these cards, there are sections for 'Getting Started' and 'See all (14)'. At the bottom of the page, there is a navigation bar with icons for back, forward, search, and other browser functions.

* **Year:** The invented year of the language.

* **Language:** The name of the language.

* **Reference(s):** The main reference paper(s) of the language.

* **Semantics:** The type(s) of semantics for the language the authors described in the reference(s).

* **Host language:** The classical language on (or to) which the language is based (or extended).

* **Paradigm:** We consider each language to belong to three types of paradigms: *imperative language*, *functional language*, and *circuit design language*.

See: [Transpiler in Qiskit](#)

A Toffoli, or controlled-controlled-not gate (ccx), is a three-qubit gate. Given that our basis gate set includes only single- and two-qubit gates, it is obvious that this gate must be decomposed. This decomposition is quite costly:

```
ccx_circ = QuantumCircuit(3)
ccx_circ.ccx(0, 1, 2)
ccx_circ.decompose().draw(output='mpl')
```

OpenQASM is an imperative programming language designed for near-term quantum computing algorithms and applications. Its main goal is to serve as an intermediate representation for higher-level compilers to communicate with quantum hardware. Current version is draft 3.0 of the OpenQASM specification.

Blackbird is a Quantum Assembly Language for continuous-variable quantum computation, that can be used to program Xanadu's quantum photonics hardware and Strawberry Fields simulator Blackbird (Killoran et al. 2019). The Blackbird repository contains:

- src: The Blackbird grammar specification in enhanced BackusNaur form
- blackbird_python: to develop Blackbird parsers for integration with Python programs
- Blackbird_cpp: libraries and header files needed to develop Blackbird parsers for integration with C++ programs

engineering

References

QMASM(Pakin 2016) fills a gap in the software ecosystem for D-Wave's adiabatic quantum computers by shielding the programmer from having to know system-specific hardware details while still enabling programs to be expressed at a fairly low level of abstraction. It is therefore analogous to a conventional macro assembler and can be used in much the same way: as a target either for programmers who want a great deal of control over the hardware or for compilers that implement higher-level languages.

intro 2021

```
operator dft(qureg q) {
    const n=#q;
    int i; int j;
    for i=0 to n-1 {
        for j=0 to i-1 {
            CPhase(2*pi/2^(i-j+1),
                   q[n-i-1] & q[n-j-1]);
        }
        Mix(q[n-i-1]);
    }
    flip(q);
}
```

define a quantum operator
name the operator `dft` (for discrete Fourier transform)
the operator will act on a quantum register named `q`

number of qubits in `q`
classical variables for loop indices
outer loop
inner loop
conditional phase rotation
angle of phase rotation
rotate if state of these qubits is 11

place qubit in state
of maximum superposition
reverse order of qubits

classical iteration
quantum operations
